

College Football Excitement Index

Jill Reiner
Raj Dasani

Competitive Games Breed the Highest Excitement

College Football Overview

- Three divisions: DI, DII, DIII
- Division I Season
 - 15 weeks in a season
 - 12 games, 8-9 coming in conference play
 - 10 conferences
- Basic Game Logistics
 - 4 15-minute quarters of back and forth play
 - 6 points for a touchdown
 - with 1 or 2 pt try after
 - 3 points for a FG

The Dataset: 2019 College Football Games

849 Regular Season College Football Games

Interesting Given Variables:

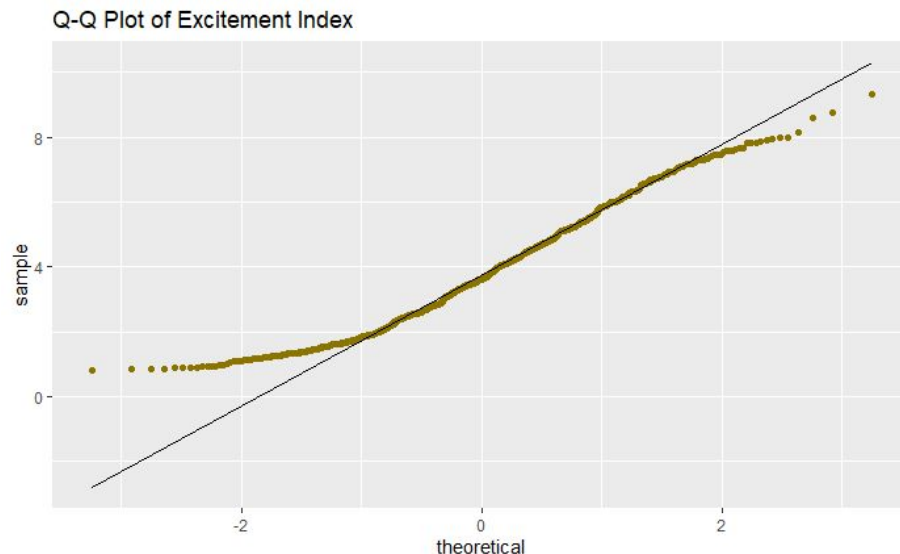

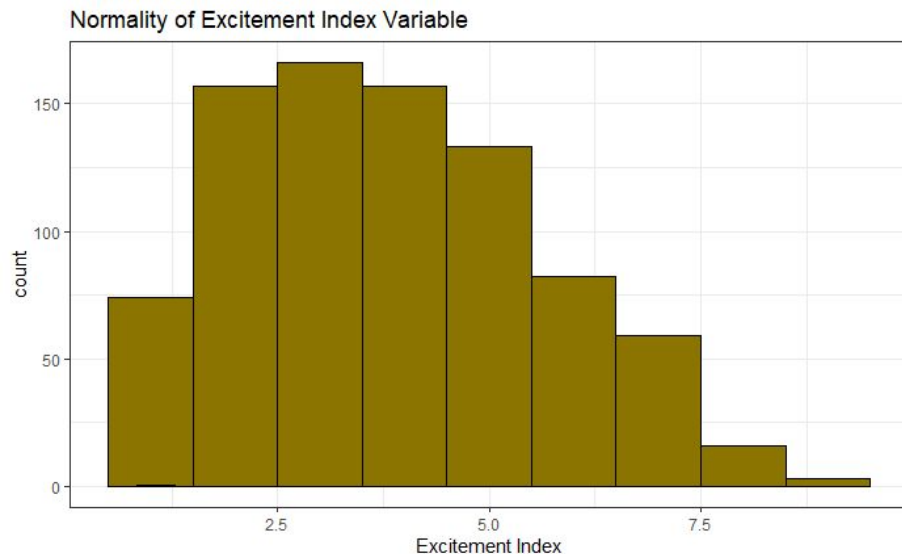

- **conference_game**: boolean indicating if teams that played were in the same conference
- **home_points, away_points**
- **excitement_index**: index of excitement based on total change in win probability
- **home_1_points, home_2_points, away_3_points, away_4_points**: points for each quarter by each team
- **score_difference**: absolute value

Created Variables:

- **margin_1st_half**: home 1st half points - away 1st half points
- **margin_game**: home - away
- **comeback**: boolean indicating if team winning in first half is different than second half
- **overtime**: boolean indicating if game went into overtime (if total points does not equal total quarter points)

The Response Variable: Excitement Index

- Index of Excitement based on total change in win probability
- Approximately Normal
- Most Unique/Unknown Variable in our Dataset to us

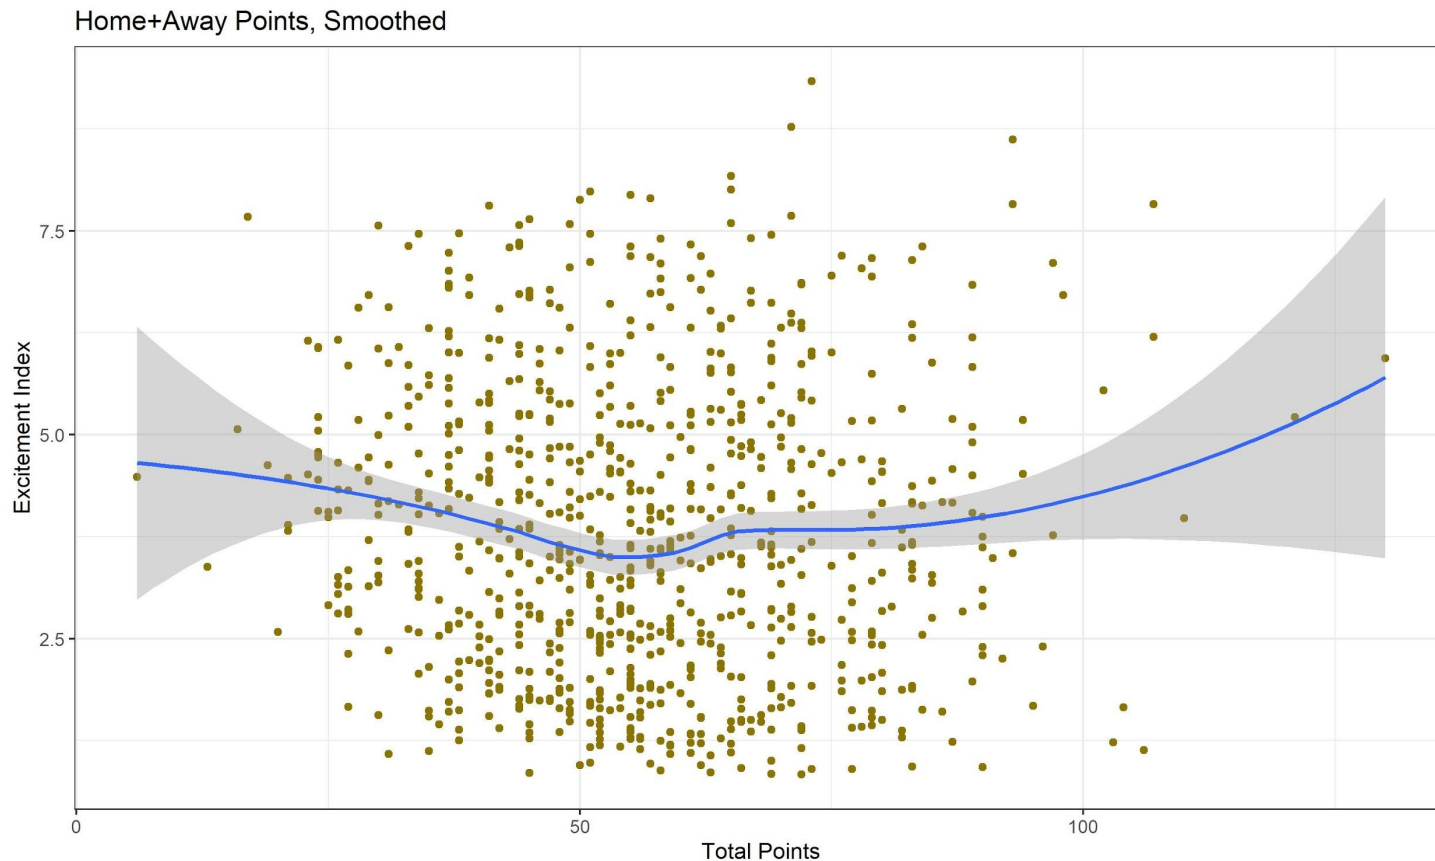

Exploratory Data Analysis

Common Assumptions Surrounding Excitement

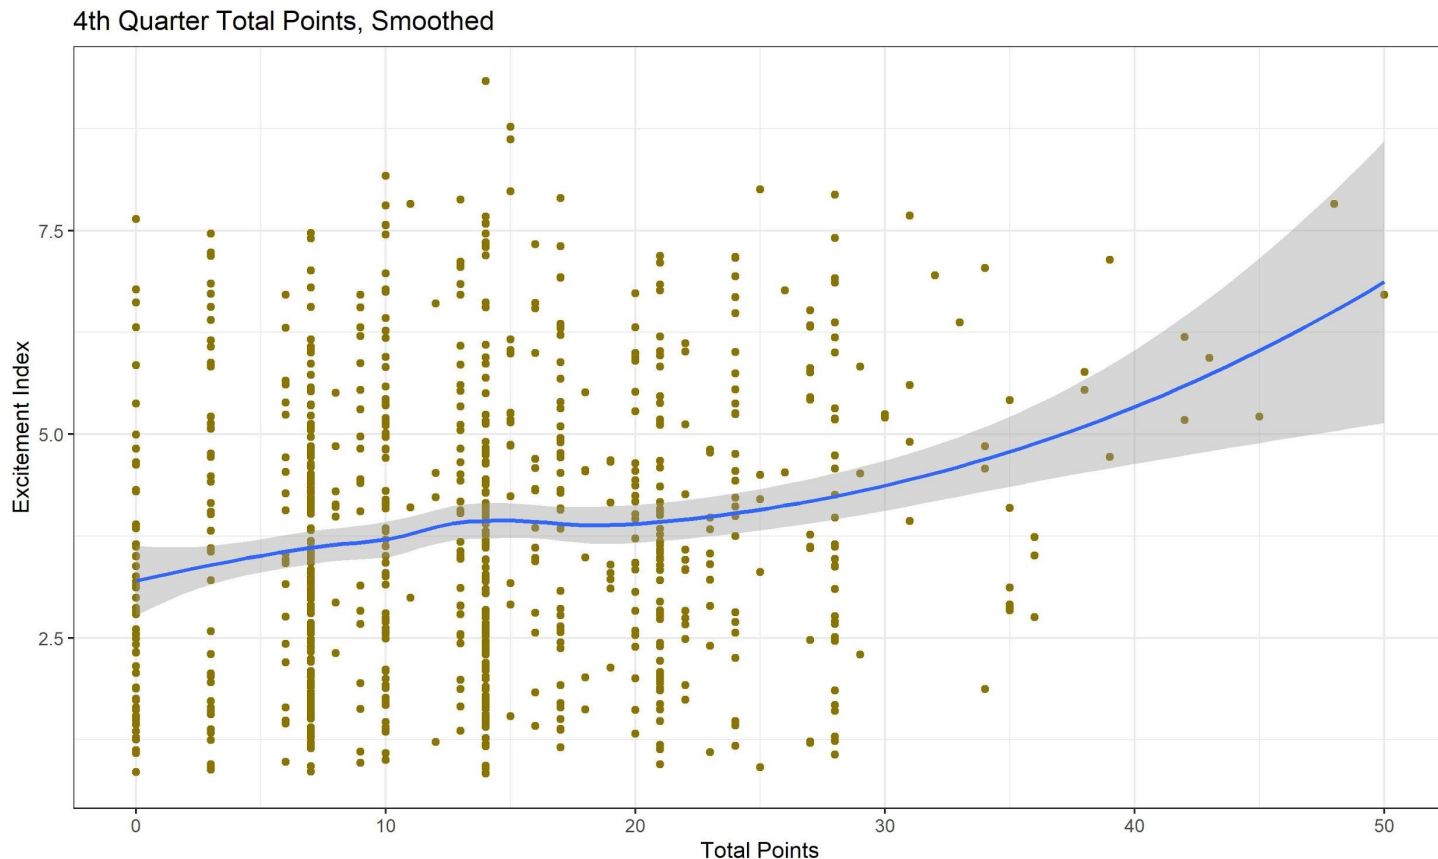

- 1) The more points scored in a single game, the more exciting the game.
- 2) If the home team wins, the more exciting the game.
 - a) Aka: Crowd excitement plays into the excitement index.
- 3) If the game occurs at a later week in the season, the more exciting the game.

Assumption 1 Debunked: Points, on its own, does not lead to Excitement

4th Quarter Points showed some correlation when teams totaled 30+ points

- Back and forth games and successful big comebacks probably fill up that 30+ range

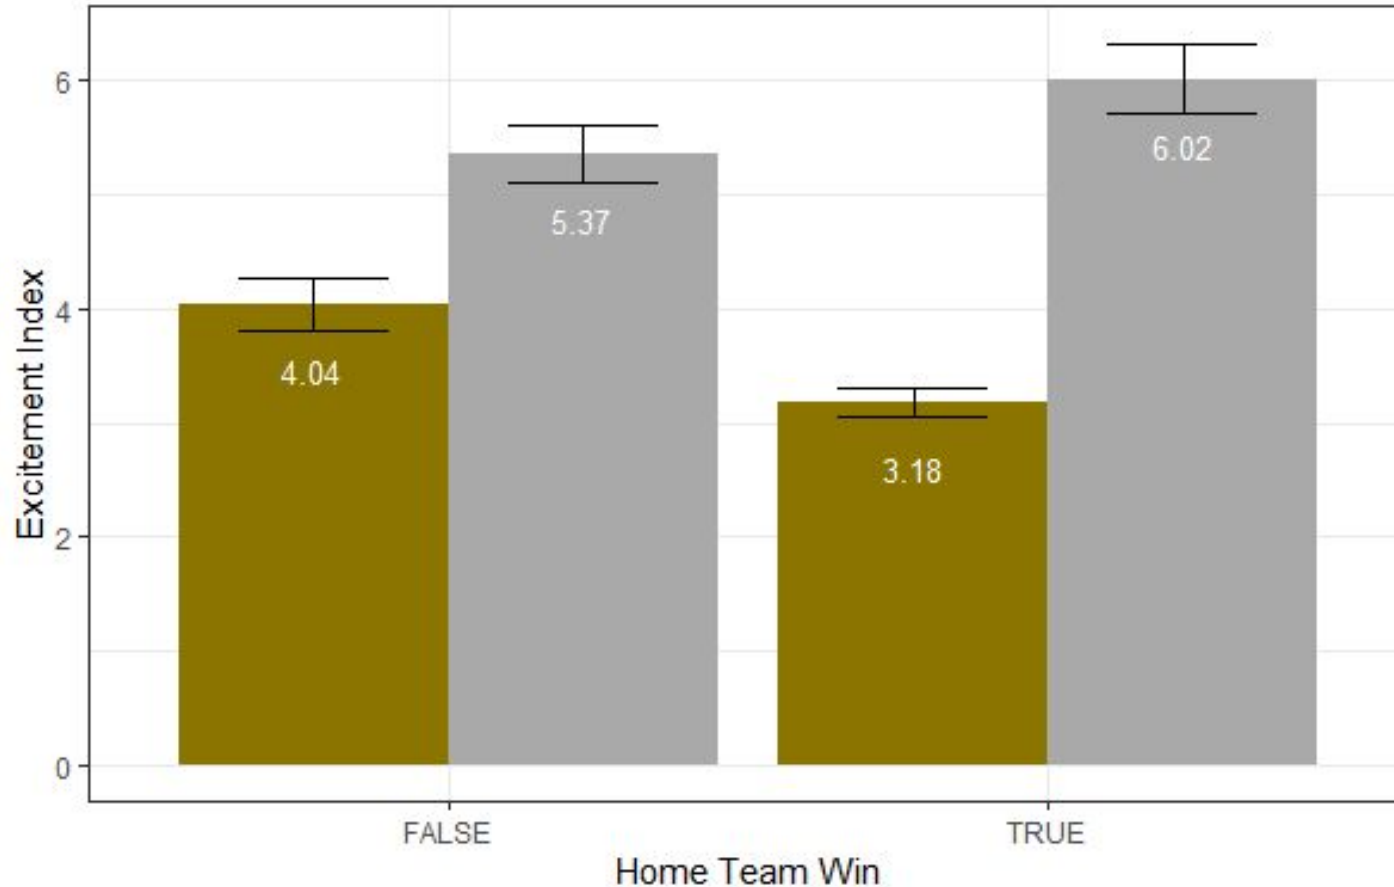

Assumption 2 Debunked: Home Team Wins are NOT the Most Exciting

- Home Advantage -> A home team winning has less fluctuation to win probability model used to define Excitement Index

Trends of Home vs Away Wins Reversed when considering Comeback games

95% Confidence Intervals

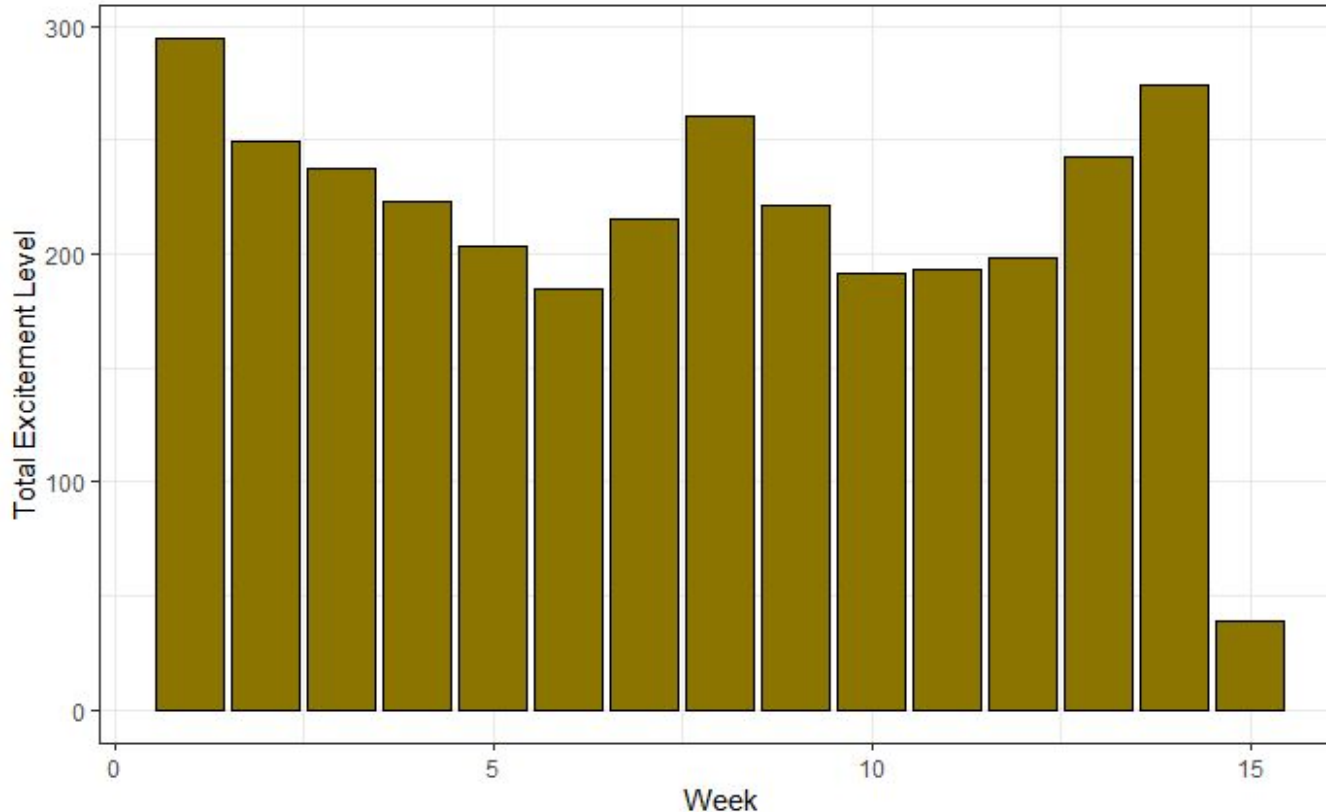

- If either home or away team won, and it was a comeback: more exciting

Comeback

Assumption 3 Challenged: Total Excitement Peaks in Early and Late Season

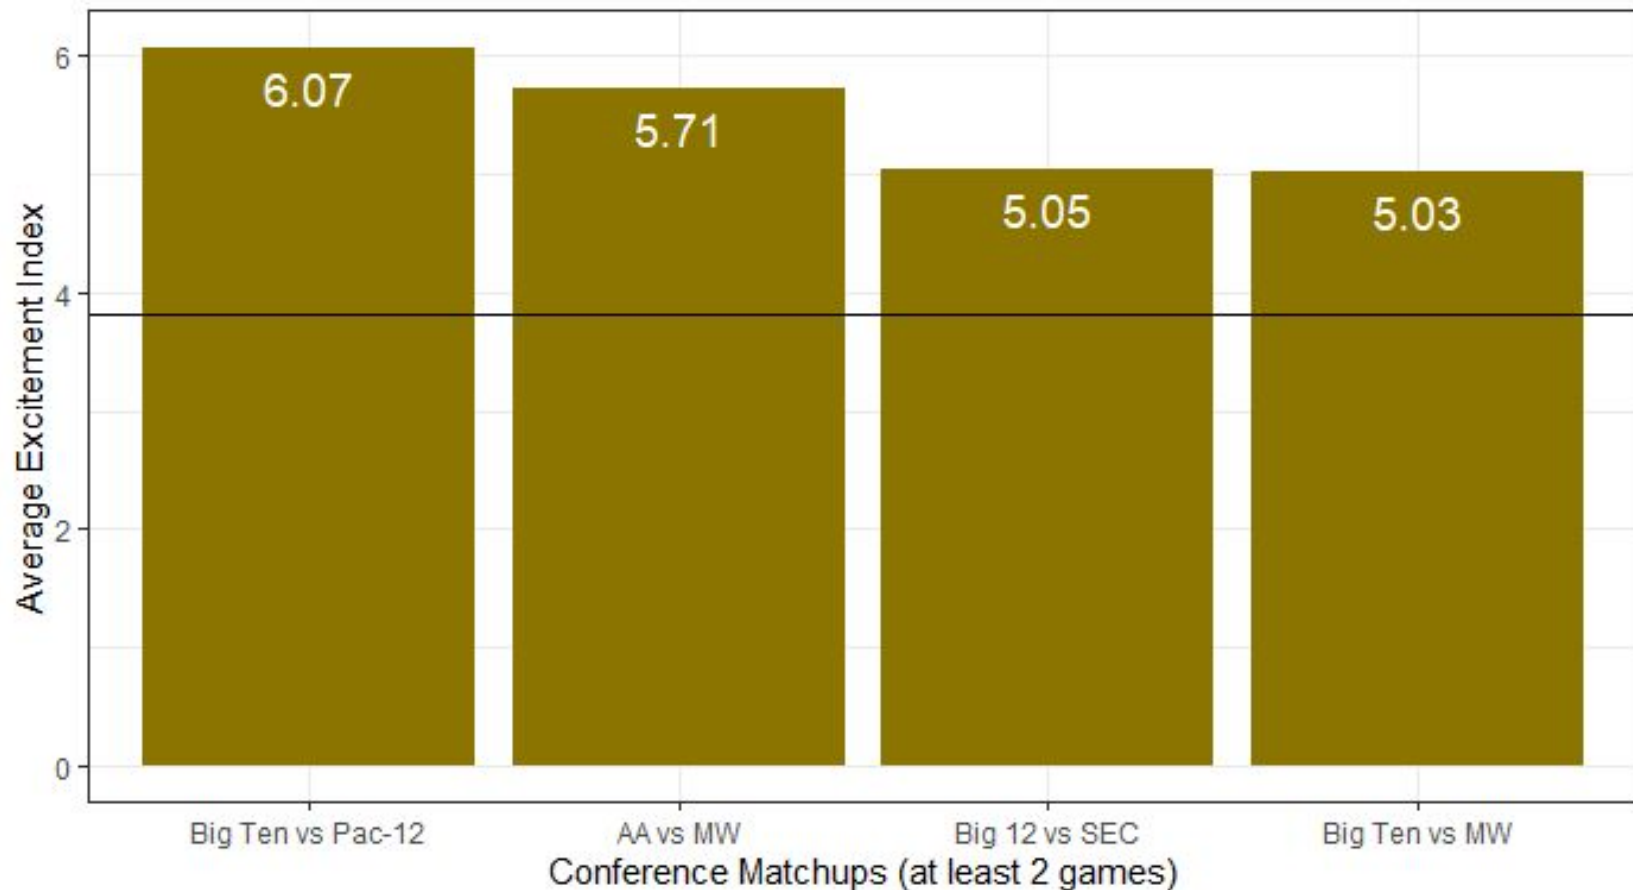

- Confounding Variable: Number of Games
- All teams play first and last weeks, but teams have bye weeks throughout season
- In 2019, week 8 seemed particularly exciting

Assumption 3 Debunked: Average Excitement did not vary much throughout the season

Most Exciting Inter-Conference Matchups

H.Line at Average Excitement Index for All Games, about 3.96

Pac-12, Big 12, ACC had the most above average games in terms of Excitement Index

- Power 5 conferences: top conferences in college football
- **Blue line:** average Excitement Index across these 5 conferences
- Competitive vs. Top-Dominated Conferences

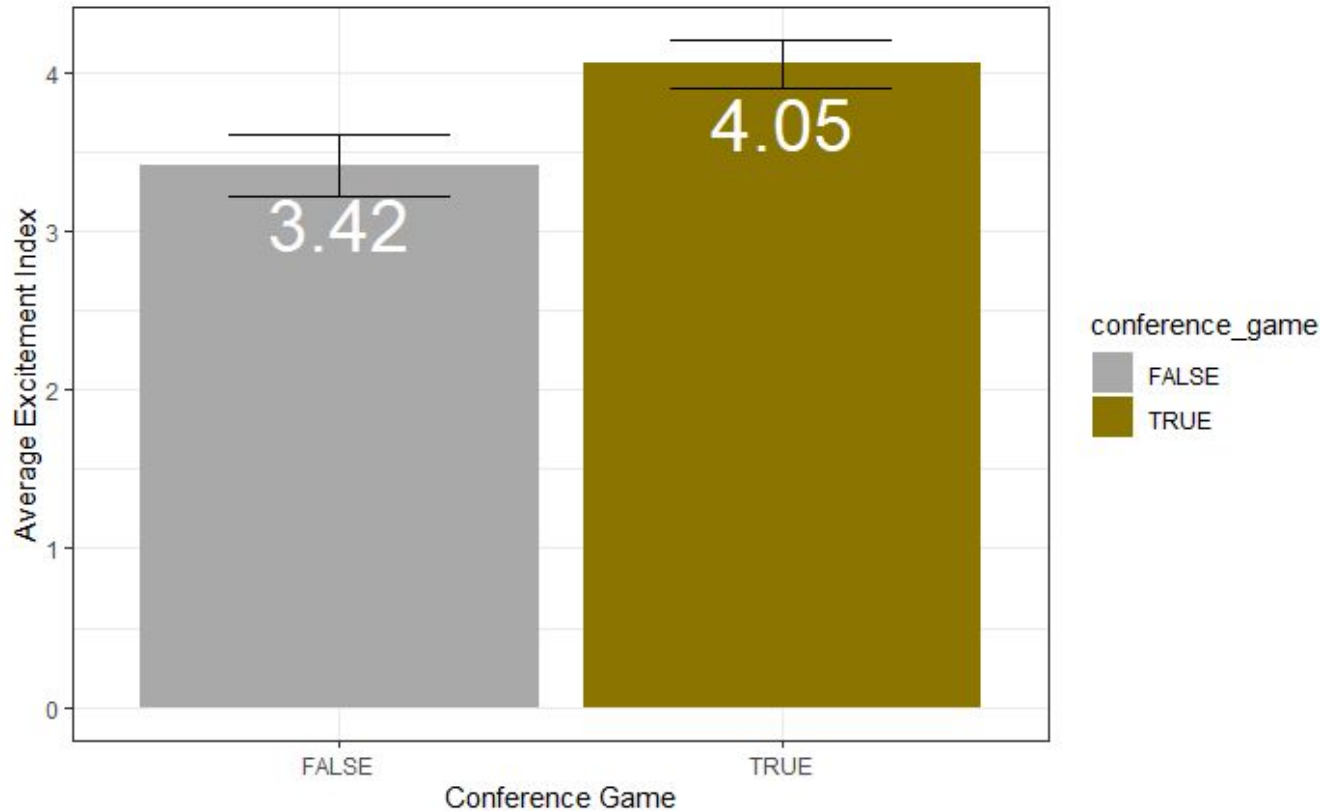

Linear Modeling

Variable Selection: Score Difference

- Strong negative correlation
- “Blowout” games tend to be not so exciting from a fan standpoint
- **Included** in our final model

Variable Selection: Conference Games

- We initially thought conference games would be an important factor, and it looked to be as the difference was **95% significant**

Insignificant Difference Between Conf. and Non-Conf. Games' Regression

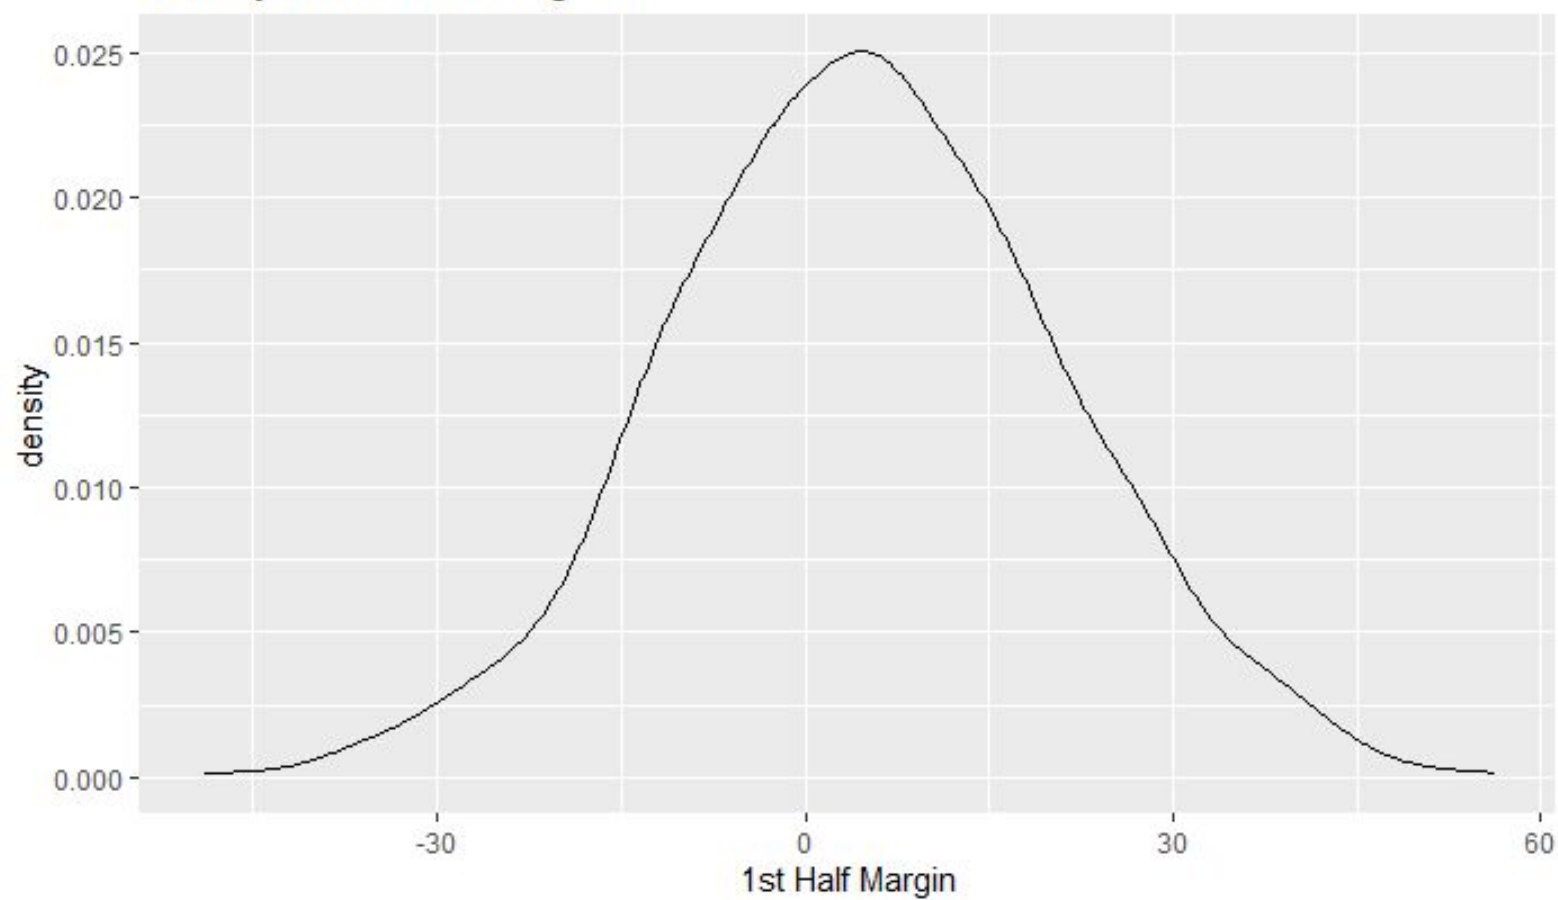

- Small margin between best fit lines between conference and non-conference games in terms of EI
- Did not add to our Model (slope of -0.01)
- **Not included** in our final model

Variable Selection: Comebacks

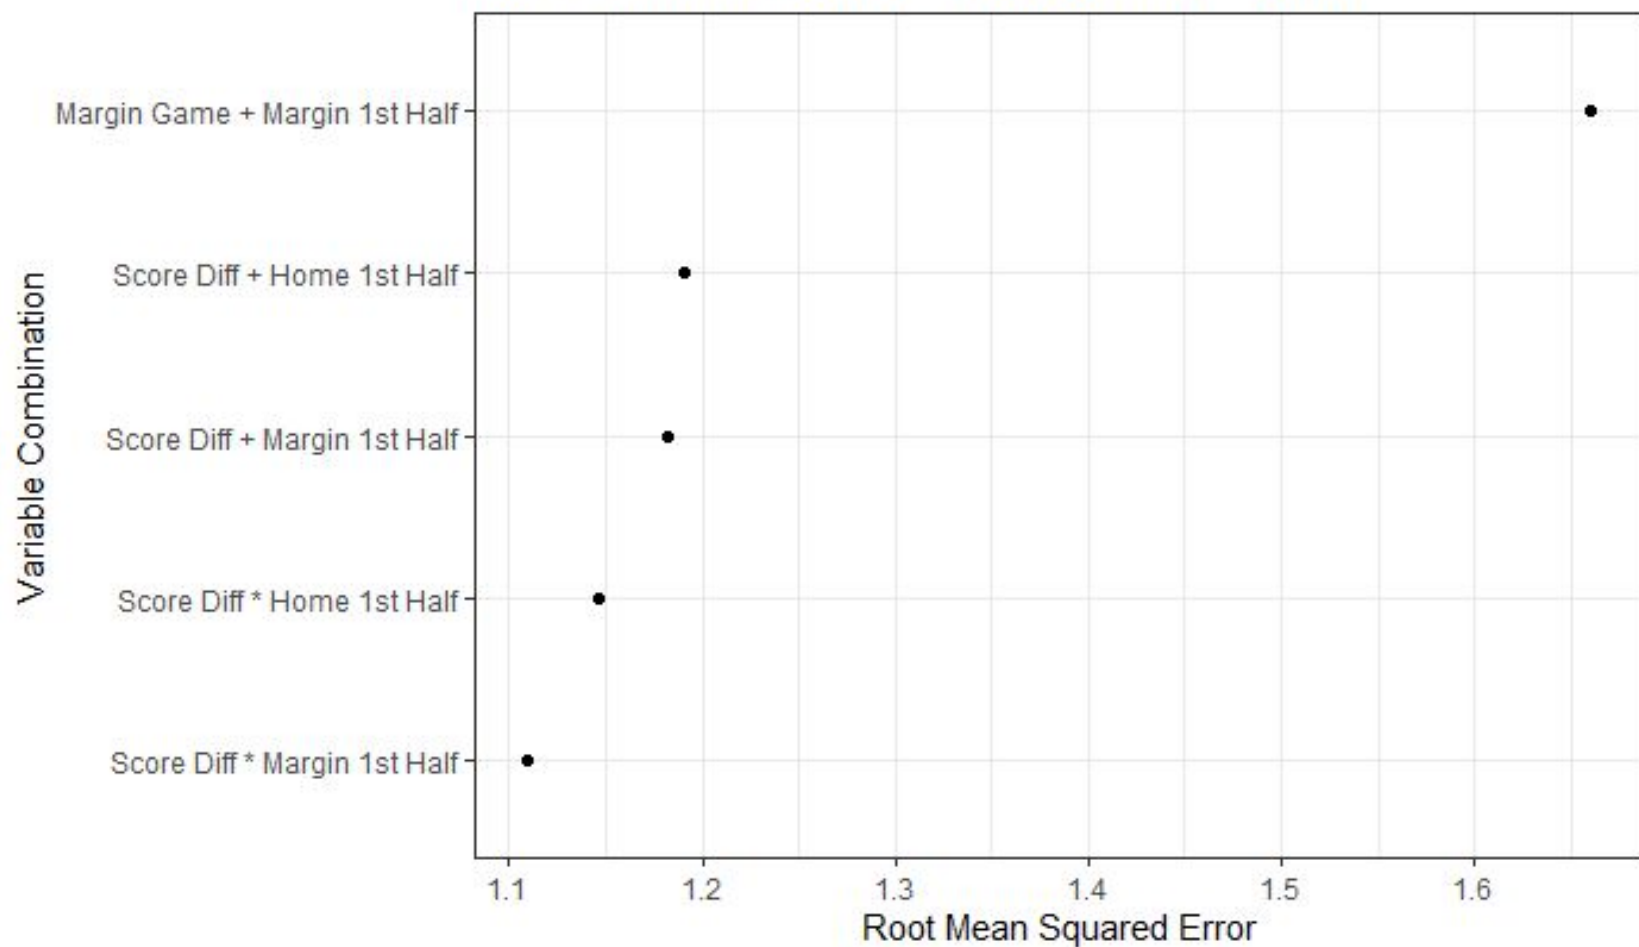

- Large margin between comeback and non comeback games in terms of EI
- Included in our final model
- Big Gap led us to test and add a quantitative stat related to this stat

Density of 1st Half Margins

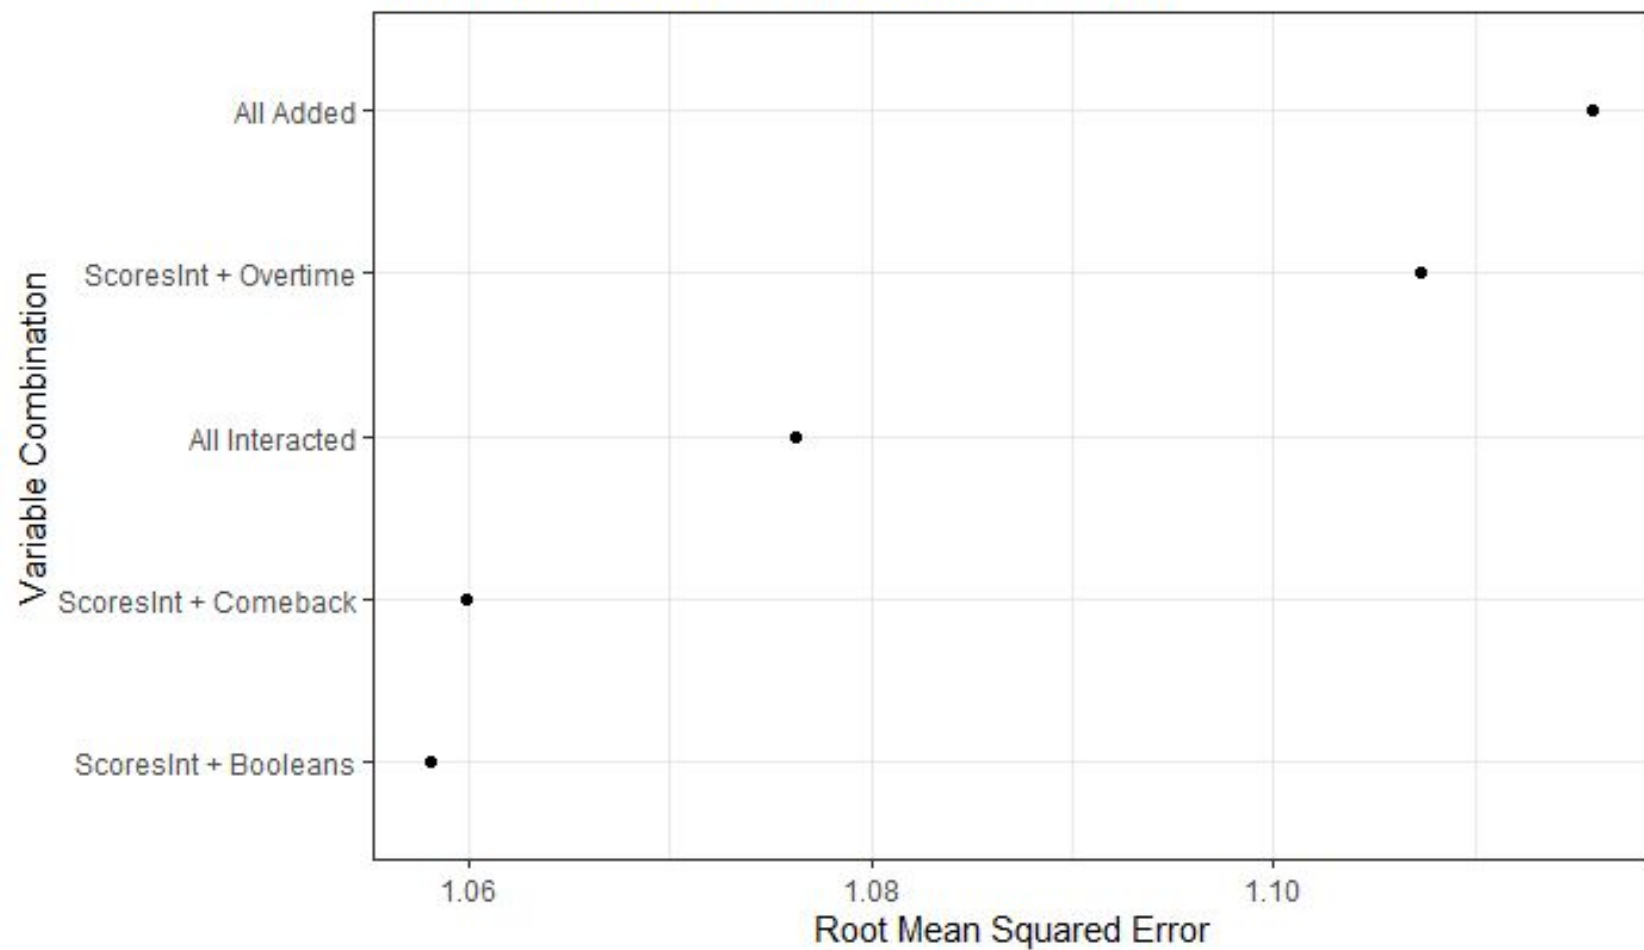

RMSE Values of Score Variables Combination

RMSE Values of All Variables Combination

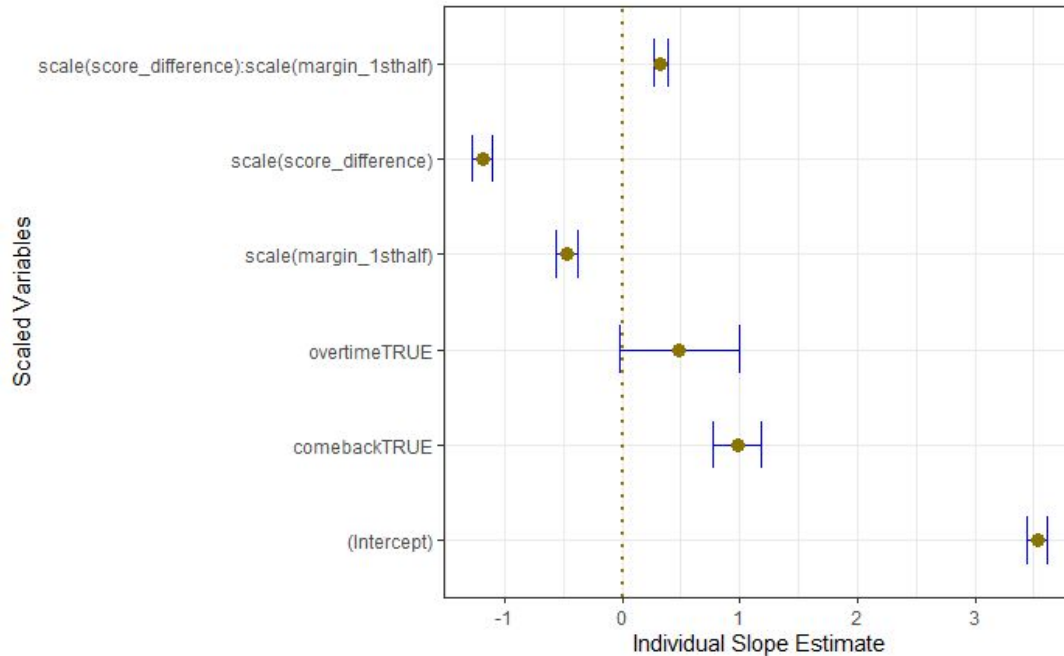

Final Regression Model

$$\begin{aligned} \text{excitement index} = & \\ & \text{comeback} + \text{overtime} + \\ & (\text{score difference} * \text{margin 1st half}) \end{aligned}$$

**Score Difference and Margin 1st Half are Scaled

Model Results

Slopes in order of importance/significance

Score Difference: -1.18

1st Half Margin: -0.47

Comeback: 0.98

Score Difference * 1st

Half Margin: 0.33

Overtime: 0.49

Intercept: 3.53

Predicted vs. Observed Excitement Index

- Pretty strong relationship between our model's predicted excitement index and the observed excitement index
- Does not predict the extremes well, especially the games with a high excitement index
 - Starting at around **x = 6.0**

Comeback Games and Close Games are Predicted to be More Exciting

- As score difference increases, predicted EI decreases
- **Comeback games and games with a low point differential** are predicted by our model to be the most exciting

Overtime Games and Close Games are Predicted to be More Exciting

Only games where score difference was within one possession

- As score difference increases, predicted EI decreases
- **Overtime games** and **games with a low point differential** are predicted by our model to be more exciting

Conclusions

- 1) The variables that had the greatest effect on Excitement Index were **Comeback**, **Overtime**, and our Interaction of **Score Difference** and **1st Half Margin**
- 2) The total point scoring in a game, the home team winning, and the later the week in the season does not correlate with a higher Excitement Index
- 3) A linear model was a good representation of the middle excitement levels, but not a great representation of the least and most exciting ones

Future Research

- 1) If we were to do additional modeling, we would look into a logarithmic/quadratic version
- 2) Another interesting variable that we thought could have an impact on Excitement Index was **rank**
 - a) whether a team was considered to be an “underdog”
 - b) if teams were ranked closely (better matchup)

Thanks!
